Classifiers in four varieties of Chinese

Lisa L.-S. Cheng and Rint Sybesma
NWO-IIAS-ULCL/Leiden University, The Netherlands

1. Introduction

This chapter deals with the use of classifiers in four varieties of Chinese, viz., Mandarin, Wu, Min and Cantonese (or, “Yue”). The main aim is to account for the distribution and interpretation of the different forms of nominal expressions in these languages, as well as for the variation that they display in this regard. To this end, we investigate the question of what parameters play a role and attempt to find deeper reasons for some of the systematic contrasts.

It is generally assumed that there are seven major Chinese language groups (or “dialects”), four of which will be looked at in this paper. The term “Mandarin” is ambiguous: it either is an alternative name for the natural variety of Chinese otherwise referred to as “the Northern-Chinese dialect”, or it is the name for the standard language, adopted as the official language on the mainland as well as on Taiwan. Roughly speaking, as a natural (as opposed to standard) language, Mandarin is spoken north of the Yangtze River as well as in the southern provinces of Yunnan and Guizhou. Wu is spoken in Zhejiang and the southern tip of Jiangsu. Min is the language of Fujian and neighboring parts of Guangdong, and of Hainan and Taiwan. Cantonese is spoken in most of Guangdong and Guangxi, and in Hong Kong. For an excellent introduction to several aspects of Chinese and its varieties, see Norman 1988.

Despite the fact that the area where Mandarin is spoken is vast, the internal variation is not very great: in essence, the Mandarin sub-varieties are mutually intelligible. This does not apply to the other dialect groups (see Ramsey 1987 for a suggestion why this would be so): the respective areas in which each of these is spoken is much smaller, but the variation is enormous, typically to the point of mutual unintelligibility. This is especially true of Wu and Min, which are standardly divided into Northern and Southern Wu and Northern and Southern Min.

Unless explicitly mentioned otherwise, our Mandarin data belong to the variety spoken in the north-northeastern regions of China. For Wu, we concentrate on the Southern Wu variety of Wenzhou, but now and then we mention Shanghainese, as a representative of the northern branch. The Min data belong to the Southern Min variety spoken on Taiwan. The variety of Cantonese we use is spoken in Hong Kong.

* This chapter incorporates most of the arguments and conclusions in Cheng and Sybesma 1999.

In gathering and sorting out the data, we received help and advice from many people, which we gladly and gratefully acknowledge. In particular we would like to acknowledge the input from the following colleagues:

Wu: We thank You Rujie for sharing with us his Wu expertise in general and for providing and discussing the Wenzhou data. Thanks a lot! For Shanghainese we are especially indebted to Hua Dongfan. We also discussed Shanghainese with You Rujie, Eric Zee, Lu Bingfu and Duanmu San.

Min: The data were provided (and checked with other informants) by C.-C. Jane Tang. Thanks are also due to Tang Ting-chi. Cantonese: Thomas Lee and Sze-Wing Tang helpfully provided judgments.

We would furthermore like to thank the following colleagues for more general comments and discussion: Thomas Lee, Jane Tang, Dylan Tsai and especially Richard Kayne, Guglielmo Cinque and Moira Yip.

Sybesma’s research was partly supported Prof. P. Muysken’s Spinoza Research Program “Lexicon and syntax”, and partly by his own “Vernieuwingsimpuls”-project on syntactic variation in southern China, co-funded by the Dutch Organization for Scientific Research NWO, Universiteit Leiden (main sponsors) and the International Institute for Asian Studies, IIAS.

1 The three varieties of Chinese not mentioned are Hakka, spoken in the area where the provinces of Jiangxi, Guangdong and Fujian border, Gan, spoken in Jiangxi, and Xiang, the language of Hunan.
2. The facts

In this section we lay out the facts which will concern us in this chapter, concentrating on the correlations between form, interpretation and distribution of three different types of nominal expressions in Mandarin, Min, Wu and Cantonese: bare nouns (to be referred to as “Bare NPs”), phrases consisting of a classifier and a nominal (“Cl-NPs”) and expressions made up of a numeral, a classifier and a nominal (“Num-Cl-NPs”). We present the facts language by language, going from North to South.

2.1. Mandarin

Bare NPs. As the following examples show, Bare NPs may receive an indefinite, a definite or a generic interpretation. What interpretation it gets is essentially determined by the nature of the predicate; in this paper we will not go into this matter. In sentences with an unbounded activity verb as in (1a), the Bare NP is interpreted as indefinite. In bounded events, like the one expressed in (1b), the Bare NP gets a definite reading. With unbounded states, the Bare NP is generic, as is shown in (1c). (For discussion of (1b), see Sybesma 1992, 176-178.)

(1) a. Hufei maishu qu le
   Hufei buy book go SFP2
   ‘Hufei went to buy a book/books’

b. Hufei he-wan-le tang
   Hufei drink-finished-PRF soup
   ‘Hufei finished the soup’

c. wo xihuan gou
   I like dog
   ‘I like dogs’

In preverbal position, however, Mandarin Bare NPs cannot be interpreted as indefinite. They either get a definite or a generic interpretation.

(2) a. gou yao guo malu
   dog want cross road
   ‘The dog/the dogs want/s to cross the road’
   NOT: ‘A dog/dogs want/s to cross the road’

b. gou jintian tebie tinghua
   dog today very obedient
   dog today very obedient
   ‘The dog/dogs was/were very obedient today’ (NOT indefinite)

c. gou ai chi rou
   dog love eat meat
   ‘Dogs love to eat meat’

Cl-NPs. Interpretationally, the Cl-NP in Mandarin is limited to a non-specific indefinite reading. As a result, it is limited distributionally, to the object position in unbounded activity predicates, as is exemplified in (3): (3a) is fine, but in the bounded predicate of (3b), which forces a strong (i.e., specific) interpretation onto indefinites (Sybesma 1992, 176-178), a Cl-NP is not possible. Cl-NPs cannot get a generic interpretation either. In preverbal position, Cl-NPs are also out.

(3) a. gou yao guo malu
   dog want cross road
   ‘The dog/the dogs want/s to cross the road’

b. gou jintian tebie tinghua
   dog today very obedient
   ‘The dog/dogs was/were very obedient today’ (NOT indefinite)

2 We use the following abbreviations in the glosses: CL = classifier; PRF = perfectivity/boundedness marker; SFP = sentence final particle. In case it seems useful to provide the meaning of the classifier, it is added in superscript.

Mandarin is transcribed using the pinyin system. For Cantonese we used the Romanization system developed by the Linguistic Society of Hong Kong. Transcribing Wenzhou we use the IPA. The Min transcription was provided by Jane Tang (for Min, there does not seem to be a standard); the capital N stands for nasalization.

Tones have been left unmarked except in the Wenzhou data, where they are marked using superscript numbers.
(3) a. wo xiang mai ben shu
   I want buy CLvolume book
   ‘I would like to buy a book’

b. *ta he-wan-le wan tang
   he drink-finished-PRF CLbowl soup
   Intended: ‘He finished a (specific) bowl of soup’

c. *wo xihuan wan tang
   I like CLbowl soup
   Intended generic reading: ‘I love a bowl of soup’

(4) a. *zhi gou yao guo malu
   CL dog want cross road
   Intended: ‘A dog wants to cross the road’

b. *zhi gou xihuan chi rou
   CL dog like eat meat
   Intended generic reading: ‘A dog likes to eat meat’

It is not generally acknowledged that Mandarin has Cl-NPs (but see Paris 1981); Cl-NPs like the one in (3a) are often considered to be the result of phonological reduction of the numeral yi ‘one’; according to this reasoning, (3a) is the reduced form of the unreduced (5):

(5) wo xiang mai yi-ben shu
   I want buy one-CL book
   ‘I would like to buy a book’

However, the fact that, as we just saw, Cl-NP is limited to contexts which are definable in semantic, rather than phonological, terms suggests that the reduction view is wrong. There is no phonological reason, for instance, why yi could not be reduced in (3b), if (6) were the “unreduced” form of (3b).

(6) ta he-wan-le yi-wan tang
   he drink-finished-PRF one-CLbowl soup
   ‘He finished a/one (specific) bowl of soup’

More arguments for the claim that Cl-NP is a real construct in Mandarin are given in Cheng and Sybesma 1999.

Num-Cl-NPs. Mandarin Num-Cl-NP shows basically the same distribution as Cl-NP, the only difference being that it can occur in the object position of bounded predicates (as we just saw in (6)), by virtue of the fact that it can be interpreted as specific. The complete paradigm is given in (7)-(8). Num-Cl-NPs in which the numeral is yi (i.e. yi-Cl-NP) may be interpreted specific and non-specific, comparable to indefinite articles in Germanic languages; it can, of course, also be stressed and mean one.

(7) a. wo xiang mai yi-ben shu
   I want buy one-CL book
   ‘I would like to buy a book’

b. ta he-wan-le yi-wan tang
   he drink-finished-PRF one-CLbowl soup
   ‘He finished a/one (specific) bowl of soup’

c. *wo xihuan yi-wan tang
   I like one-CLbowl soup
   Intended generic reading: ‘I love a/one bowl of soup’
(8)  

a. *yi-zhi gou yao guo malu  
one-CL dog want cross road  
Intended: ‘A dog wants to cross the road’

b. *yi-zhi gou xihuan chi rou  
one-CL dog like eat meat  
Intended generic reading: ‘A dog likes to eat meat’

Summary. In Mandarin, Bare NPs can be interpreted as definite, indefinite or generic. Num-Cl-NPs and Cl-NPs are invariably indefinite. A difference between the two is that Num-Cl-NPs can be both specific and non-specific, Cl-NPs are limited to a non-specific interpretation. All indefinites occur in postverbal position only.

2.2. Wu

Bare NPs. The distribution and interpretation of Bare NPs in Wu is the same as in Mandarin. As objects, they can be interpreted as indefinite, definite and generic, depending on the nature of the predicate. The following sentences are Wenzhou examples.

(9)  
a. vu² fei¹ tsau³-khe⁵ ma⁴ si¹ fiuⁿ² ba⁴  
Vu Fei go buy book SFP SFP  
‘Vu Fei went to buy a book/books’

b. ēº dei⁶ thu¹ ha⁷ jy² ba⁴  
I take soup drink up SFP  
‘I finished the soup’

c. ē° si²-cy¹ kau³  
I like dog  
‘I like dogs’

As to (9b), in bounded predicates Wu disallows objects in postverbal position. Instead, the object appears in preverbal position, following the element dei⁶ meaning ‘take’.

In preverbal position, Wu displays the same interpretational pattern for Bare NPs as Mandarin, as is exemplified by the following Wenzhou data. They either get a definite or a generic interpretation; an indefinite reading is excluded.

(10)  
a. kau³ i⁵ tshi⁷ niou⁸  
dog want eat meat  
‘The dog/the dogs want/s to eat meat’ (NOT: indefinite)

b. kau³ ke⁷-ne⁸ de⁸-bi⁸ ten²-ku³  
dog today very obedient  
‘The dog/the dogs was/were very obedient today’ (NOT: indefinite)

c. kau³ si²-cy¹ tshi⁷ niou⁸  
dog like eat meat  
‘Dogs like to eat meat’

Cl-NPs. With respect to Cl-NPs the situation is not the same in all Wu dialects. While in some varieties the facts are quite similar to those of Mandarin, Wenzhou is very different. As we saw, in Mandarin Cl-NPs

---

3 Without the help of You Rujie we would not have been able to present a complete set of Wenzhou data; especially the presentation of the tone facts would have been much more sketchy.

4 For discussion of the Mandarin counterpart, ba, see Sybesma 1999.
can only be interpreted as indefinite and their distribution is limited to postverbal position. In contrast, Wenzhou Cl-NPs may occur in both preverbal and postverbal position, and it may be interpreted as definite as well as indefinite (non-specific). Let us look at Cl-NPs in postverbal position first.

(11) a. ɬ̬ì⁴ maxi⁴ paŋ³ si¹ le² tshì⁵
   I want buy CLvolume book come read
   ‘I would like to buy a book to read’

b. ɬ̬ì⁴ dei⁶ yì⁷/yì⁷ thu³ ha⁷ jì² ba⁴
   I take CLbowl/CLPL soup drink up SFP
   ‘I finished the (bowl of) soup’

c. *ɬ̬ì⁴ si³-cy¹ ha⁷ yì⁷/yì⁷ thu³
   I like drink CLbowl/CLPL soup
   Intended generic reading: ‘I like (a bowl of) soup’

The use of the Cl-NP in (11a) is similar to (3a): paŋ³ si¹ ‘CL-book’ is interpreted as indefinite. However, the Cl-NP in (11b) is interpreted as definite: whether yì ‘bowl’ or yì ‘some’ is used makes no difference, in both cases the Cl-NP combination translates as ‘the soup’ (we return to this below).

Let us look at the use of Cl-NPs in preverbal position. Like Mandarin, Wenzhou excludes both an indefinite and a generic interpretation, but unlike Mandarin, preverbal Cl-NPs in Wenzhou can be interpreted as definite.

(12) a. dyu⁸ kau³ i⁵ tsau³-ku⁵ ka¹-løy⁶
   CL dog want walk-cross street
   ‘The dog wants to cross the street’

b. *dyu⁸ kau³ si³-cy¹ tshì⁵ niou⁸
   CL dog like eat meat
   Intended generic reading: ‘Dogs like to eat meat’
   (Only possible reading: ‘The dog likes to eat meat’)

Interestingly, when Cl-NPs in Wenzhou are interpreted as definite, the tone of the classifier is affected.

Wenzhou has eight tones (Norman 1988, Pan 1991), which are divided in four different classes, which for practical reasons we will call A, B, C and D. Each of these classes is in turn divided in two sub-classes according to register, hi and lo. Thus, we have a hi-A, a lo-A, a hi-B, a lo-B, etc., and they are numbered accordingly (see table 1 and the examples): 1 for hi-A, 2 for lo-A, etc. Given a five point scale (1 = low, 5 = high), the tonal contour values given by Norman (1988, 202) are the following:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>44</td>
<td>31</td>
<td>45</td>
<td>24</td>
<td>42</td>
<td>11</td>
<td>23</td>
<td>12</td>
<td></td>
</tr>
</tbody>
</table>

Chen’s (2000, 476) values are partly different, the biggest difference being that according to him, the D-tones have a dipping contour. The values Chen provides are /313/ and /212/ for hi-D and lo-D respectively.

What happens to the tone of the classifier when Cl-NPs are interpreted as definite is that, along register lines, it invariably is pronounced as a D-tone, whatever its original tone may have been: hi-A (tone number 1), hi-B (tone number 3) and hi-C (number 5) as well as hi-D (tone number 7) surface as hi-D (number 7), while lo-A (tone number 2), lo-B (number 4) and lo-C (number 6) as well as lo-D (8) surface as lo-D (8) (You 2000; see also Pan 1991). For now, we call this process tonal neutralization; we discuss it more in section 4.1.2 below.
Let’s look at some examples. The original tone of the classifier for dogs $d\nu u$ is the lo-A (tone number 2): $d\nu u^2$. In (12a), where the Cl-NP is interpreted as definite, the tone changes to lo-D (tone number 8). If we change the tone in (12a) to its original lo-A (as we do in (13)), the sentence is ungrammatical: because of the tone, we can no longer have a definite reading and, just like in Mandarin, an indefinite reading is excluded in preverbal position.

(13) $^*d\nu u^2$ kau$^8$ i$^5$ tsau$^3$-ku$^5$ ka$^1$-loy$^6$
    CL dog want walk-cross street

In postverbal position, $d\nu u^2$ kau$^8$ ‘CL dog’ would of course be grammatical – be it with an indefinite interpretation:

(14) ň$^4$ ci$^3$ ma$^4$ $d\nu u^2$ kau$^8$
    I want buy CL DOG
    ‘I would like to buy a dog’

To illustrate the mechanism one more time, we present a minimal pair in (15) (cf. (11a)).

(15) a. ň$^4$ ci$^3$ ma$^4$ paŋ$^3$ si$^1$
    I want buy CL volume book
    ‘I want to buy a book’

b. ň$^4$ ci$^3$ ma$^2$ paŋ$^7$ si$^1$
    I want buy CL volume book
    ‘I want to buy the book’

The only difference between (15a) and (15b) is the tone on the classifier $paŋ$ ‘volume’. Its orginal tone is hi-B, 3. Keeping the original tone, the Cl-NP in (15a) is interpreted as indefinite. In (15b), $paŋ$ appears in the hi-D-tone (number 7), and the Cl-NP receives a definite interpretation.

Some classifiers inherently have a D-tone. In the appropriate context, Cl-NPs with these classifiers are ambiguous.

(16) ň$^4$ ci$^3$ ha$^7$ y$^7$/li$^7$ thu$^1$
    I want drink CL bowl/CL PL soup
    ‘I would like to drink a bowl of soup/some soup’
    OR: ‘I would like to drink the soup’

In short, Wenzhou Cl-NPs can be interpreted as definite as long as the classifier is pronounced with a D-tone. For all classifiers that do not inherently have a D-tone, this means a tone change, to be referred to as tonal neutralization (for discussion, see section 4.1.2).

Num-Cl-NPs. With respect to Num-Cl-NPs, Wu is the same as Mandarin. They are interpreted as indefinite, either specific or non-specific. Distributionally, they are limited to postverbal position. Here are some Wenzhou examples. The counterparts of (7c) and (8a,b) are also ungrammatical in Wu/Wenzhou.

---

5 The situation in Shanghainese is not as clear-cut as in Wenzhou. You Rujie (p.c.) confirms that the Shanghainese language situation is unstable, or at least that a lot of variation exists among speakers.

Qian (1997, 98-99) claims that Shanghai is like Wenzhou the way we described it in the text in that Cl-NPs can be interpreted as definite, in which case the classifier undergoes a tone change (the precise mechanics of the tonal changes being different from what happens in Wenzhou). Qian says that the younger generation uses it rarely.

One of our Shanghainese informants agrees that Cl-NP can be used with a definite reading, but is not aware of any tonal change. This is basically the picture sketched by Pan (1991).

Three of our informants do not accept Cl-NPs in a definite reading; in an indefinite reading, they are judged fine. The Shanghainese of these speakers is exactly like Mandarin.

---
It should be noted, that the classifier preceded by \( i^7 \) ‘one’ keeps its inherent tone.

(17) a. \( \hat{\eta}^4 \) ci\(^3\) ma\(^4\) i\(^7\) pan\(^3\) si\(^1\) le\(^2\) tshi\(^5\)
    I want buy one Cl\(^\text{volume}\) book come read
    ‘I would like to buy a book to read’ (non-specific)

b. \( \hat{\eta}^4 \) dei\(^6\) i\(^7\) y\(^7\) thu\(^1\) ha\(^7\) jy\(^2\) ba\(^4\)
    I take one Cl\(^\text{bowl}\) soup drink up SFP
    ‘I finished a bowl of soup’ (specific)

Summary. In Wu, Bare NPs can be interpreted as definite, indefinite or generic. Cl-NPs are interpreted as indefinite in all varieties of Wu (non-specific only); in some, like Wenzhou, they can also be interpreted as definite, in which case the tone of the classifier is affected in the sense that some neutralization takes place. Num-Cl-NPs are invariably indefinite (specific or non-specific). All indefinites occur in postverbal position only.

2.3. Min

The situation in Southern-Min is the same as Mandarin, with one exception: it has no Cl-NPs, not even in an indefinite reading (Chen 1958, Zhou 1991).

Bare NPs. Thus, just like in Mandarin (as was the case in Wu), Bare NPs can be interpreted as definite, indefinite and generic, depending, partly, on the predicative context and the position vis à vis the verb (preverbal position excluding an indefinite interpretation). The sentences in (18) and (19) run parallel to the Mandarin examples in (1) and (2); as to (18b), like Wu, Min disallows postverbal objects in bounded predicates, and, like Wu (see (9b)), it marks the object in preverbal position, using an element meaning ‘take’.

(18) a. i be bue zhu
    he want buy book
    ‘He would like to buy a book/books’

b. i ga teN lim liao a
    he take soup drink PRF SFP
    ‘He finished the soup’

c. i ai hue
    he like flower
    ‘He likes flowers’

(19) a. gau be lim zhui
    dog want drink water
    ‘The dog/the dogs want/s to drink water’ (definite only)

b. gau ai lim zhui
    dog like drink water
    ‘Dogs like to drink water’ (definite possible; indefinite excluded)

Cl-NPs. It is explicitly mentioned in the literature (e.g., Chen 1958, Zhou 1991) and confirmed by the informants that Southern-Min has no Cl-NPs: the classifier can never occur without being preceded by either a numeral or a demonstrative.\(^6\) Thus, the counterparts of Mandarin (3a) and Wenzhou (12a) are ungrammatical in Southern-Min.

\(^6\) It seems that the younger generation of Taiwan’s Min speakers who are fluent in Mandarin as well do not reject Cl-NPs in Min entirely, in which case they get a non-specific indefinite interpretation; this may be due to influence from Mandarin.
(20) a. *ua siuN bue bun zhu
I want buy CLvolume book
Intended: 'I would like to buy a book'
b. *jia gau be lim zhui
CL dog want drink water
Intended: 'The dog wants to drink water'

Num-Cl-NPs. Just like in Mandarin and Wu, Southern-Min Num-Cl-NPs receive a specific or non-specific indefinite interpretation.

(21) a. ua siuN bue jit-bun zhu
I want buy one-CLvolume book
'I would like to buy a book' (non-specific)
b. i ga jit-waN teN lim liao a
he take one-CLbowl soup drink PRF SFP
'He finished a bowl of soup' (specific)

Summary. In Southern-Min, Bare NPs can be interpreted as definite, indefinite or generic. Num-Cl-NPs are invariably indefinite, either specific or non-specific. Cl-NPs do not occur in this language, neither in an indefinite nor in a definite interpretation. As before, all indefinites occur in postverbal position only.

2.4. Cantonese

Bare NPs. Cantonese is different from all three varieties of Chinese described above in that Bare NPs cannot be interpreted as definite: they can only receive a generic and an indefinite reading.

(22) a. Wufei heoi maaai syu
Wufei go buy book
'Wufei went to buy a book/books'
b. *Wufei jam-jyun tong la
Wufei drink-finish soup SFP
Intended: 'Wufei finished drinking the soup.'
c. ngo zung-ji gau
I like dog
'I like dogs'

(23) a. *gau soeng gwo maalou
dog want cross road
Intended: 'The dog wants to cross the road'
b. gau zung-ji sek juk
dog like eat meat
'Dogs love to eat meat' (only interpretation possible)

Cl-NPs. With respect to Cl-NPs, Cantonese is similar to Wenzhou: aside from an indefinite interpretation, Cl-NPs can also be interpreted as definite. In Cantonese, however, there are no tonal effects. The indefinite use is illustrated in (24a); the definite interpretation is exemplified in (24b,c) (cf. (22b) and (23a); also, cf. the Wenzhou sentences in (11b) and (12a)).

(24) a. ngo soeng maaai bun syu lei taai
I want buy CLvolume book come read
'I want to buy a book to read'
b. Wufei jam-żyun wun/di tong la
   Wufei drink-finish CLbowl/CL PL soup SFP
   ‘Wufei finished the soup’

c. zek gau soenggwo maalou
   CL dog want cross road
   ‘The dog wants to cross the road’

**Num-Cl-NPs.** Num-Cl-NPs have the same distribution and interpretation in Cantonese as they do in the other varieties of Chinese, discussed above.

**Summary.** In Cantonese, Bare NPs can be interpreted as indefinite or generic, but not as definite. Cl-NPs can be either definite or indefinite (non-specific), with no tonal repercussions. Num-Cl-NPs are invariably indefinite (specific or non-specific). As in all the other varieties, all indefinites occur in postverbal position only.

### 2.5. Summary

The form-interpretation correlations are summarized in the table below.

</table>

Depending on the perspective chosen these facts can be described in different ways. From the perspective of the formal properties, we can summarize them as follows.

I. **Num-Cl-NPs** are the same in all languages: they only allow for an indefinite reading. Below we present a proposal to explain why that is the case.

II. **Cl-NPs** show more variation. First of all, in Min they are not possible at all. In Mandarin, Cantonese and Wu they occur, but while in Mandarin they can only receive an indefinite reading, in Cantonese and Wenzhou they can be interpreted as definite as well. Wenzhou has the extra feature of tonal neutralization affecting the classifier in definite Cl-NPs, while the indefinite counterpart does not involve such tonal neutralization. In Cantonese, the tones are unaffected. Below, we propose an explanation as to why Cl-NPs can be interpreted as indefinite and definite; why Cl-NPs cannot be definite in Mandarin while they can in Cantonese and Wenzhou; and what the significance of the tonal neutralization in Wenzhou definite Cl-NPs is.

III. **Bare NPs** can be interpreted as indefinite and generic in all four languages. As far as the definite inter-
pretation is concerned, Bare NPs can be so interpreted in Mandarin, Wenzhou and Min, i.e. in the two languages in which Cl-NPs cannot be interpreted as definite (Mandarin and Min) and in the language in which the definite Cl-NP involves tonal neutralization for the classifier. In Cantonese Bare NPs cannot be interpreted as definite.

Below, we investigate the question as to how it is possible that Bare NPs can be interpreted as indefinite, definite and generic as well as the question why Cantonese is different.

From the perspective of the interpretative properties, the facts in the table above may be summarized as follows.

I. To express an indefinite reading, the four languages are basically the same: Num-Cl-NPs, Cl-NPs and Bare NPs can be interpreted indefinitely in all cases, the only exception being Min, in which Cl-NP-phrases do not occur at all. Indefinites are only found in postverbal position.

II. The generic interpretation is even more simple: all four languages use only Bare NPs to express genericity.

III. The way to express the definite reading is more complicated. In Mandarin and Min, definiteness is expressed with Bare NPs only. Cantonese employs Cl-NPs to express definiteness. Wenzhou does both, but in the definite Cl-NPs the tone of the classifier is affected.

Below we discuss the form, interpretation and distribution of the different nominal expressions in the four languages discussed here. We will focus on definite and indefinite phrases, because they show interesting variation. Before investigating the variation, however, we want to take a closer look at the nature and use of classifiers.

3. Classifiers

3.1. Classifiers and the functional domain of N

3.1.1. The function of classifiers

So far we have been using the term classifier loosely, as a cover term for two types of elements, traditionally referred to as “classifiers” and “measure words” and dubbed “count-classifiers” and “mass-classifiers” in Cheng and Sybesma 1998 (“count-classifiers” and “mass-classifiers” were subsequently abbreviated to “classifiers” and “massifiers” respectively). The difference between the two elements is the following (for some discussion, see Croft 1994; Tai and Wang 1990). Measure words are used to make masses countable; this is the case in Chinese as well as in other languages.

(25) a. a glass of water  
  Dutch  
  a glas water  
  c. yat bui seoi  
  Cantonese  
  one cup water

As these examples show, if you want to count a mass like water, you need a counter, a unit to count it with. Measure words make masses countable by creating a unit by which they can be counted. These units have to be created because masses, by their very nature, do not come naturally in units by which they can be...
counted. WATER does not naturally come in countable units, so we force it into glasses or bottles (or liters or barrels).

Aside from measure words, languages like Chinese have classifiers. In such languages count nouns look like mass nouns in that they too need a counter when you want to count; the examples in (26) show that counting without a counter, in this case the classifier for books, leads to ungrammaticality.

(26) a. yi *(ben) shu Mandarin
b. i7 *(pan3) si1 Wenzhou
c. jit *(bun) zhu Southern-Min
d. yat *(bun) syu Cantonese
one CL volume book

The difference with measure words is that classifiers do not create any unit to count by. Unlike mass nouns, count nouns have a built-in semantic partitioning, they come in naturally countable units. Classifiers, then, simply name the unit that the semantic representation of the noun naturally provides.

In other words, just like other languages, Chinese languages have count nouns and mass nouns in the sense that they have nouns whose semantic representation does not have a built-in partitioning in natural units and nouns whose semantic representation does have such partitioning. Languages like Chinese, however, need a counter for both noun categories; it simply is a property of these languages that they cannot count anything without the intervention of a counter. In the case of mass nouns, these counters – the measure words, or mass-classifiers – create their unit of counting, in the case of count nouns the counters – the classifiers, or count-classifiers – simply name the unit that the semantic representation of the noun provides.

They are called “classifier” because different nouns have different count-classifiers, depending on the shape or any other property of the individual units that come with the natural partitioning. In Mandarin, for instance, long tall things like humans are counted with a classifier, ge, that goes back to a word meaning ‘bamboo’. In this sense they can be seen to classify.

In the following we will use the term “classifier” either as a cover term for measure words and classifiers or as a shorthand for count-classifier. Only when it really matters we will strictly distinguish between count-classifiers and mass-classifiers.

3.1.2. Why count-classifiers?

The question that comes up immediately is why we need count-classifiers. If the semantics of the nouns in question already involves a partitioning in natural units, why do we need elements to name them when we start counting?

Doetjes (1996) argues that, in general, for count nouns to be countable, the partitioning that is part of their semantic denotation must be (made) syntactically visible; numerals require the presence of a syntactic marker of countability. She further argues that this countability marker can be realized in different ways: in some languages, number morphology performs this function, while other languages use count-classifiers. In other words, count-classifiers and number morphology have the same function of serving as a syntactic countability marker.

The idea that number and count-classifiers are associated is not new, as Doetjes points out. Greenberg (1963) notes that there is a tendency for languages without grammatical number to make use of count-classifiers. Interesting evidence also comes from language development. Ikoro (1994) describes the development of Kana, a Nigerian Cross River language, which lost its noun class related number morphology and replaced it with a count-classifier system, while other languages of the same family kept the original system and did not develop count-classifiers. Peyraube (1997) suggests that the development of count-classifiers in Chinese is related to the loss of an element which may have been a plurality marker.

---

8 We are aware of the fact that languages such as Finnish and Hungarian do not have plural markings when combined with a numeral. However, these languages would still count as “Number” languages. The absence of the plural marking may be a matter of agreement.
3.1.3. Association with Number

Aside from the considerations given above, there are other indications that classifiers have something to do with number (for discussion, see Paris 1981; 1989). First of all, in Wenzhou and Cantonese definite Cl-NP phrases, it is the classifier which determines whether we are dealing with plural or singular.

(27) a. bun syu
   CLvolume book
   ‘the book(*)s’

b. di syu
   CLPL book
   ‘the book(*)s’

(28) a. pa
   CLvolume book
   ‘the book’

b. li
   CLPL book
   ‘the book(*)s’

All Chinese languages have a general classifier for the unspecified plural; the same form is used for all nouns, count-nouns and mass-nouns alike. In Cantonese it is di, in Wenzhou liê’, in Mandarin xie. A “canonical” classifier like Cantonese bun ‘volume’ in (27a) signals singular, whereas the plural classifier di in (27b) marks the whole phrase as plural. The Wenzhou examples in (28) illustrate the same thing. Mandarin can be shown to work in exactly the same way, with indefinite Cl-NP phrases.

(29) a. wo xiang mai ben shu
   I want buy CLvolume book
   ‘I would like to buy a book’

b. wo xiang mai xie shu
   I want buy CLvolume book
   ‘I would like to buy some books’

The only difference between these sentences lies in the choice of the classifier. These facts strongly suggest that the classifier is the locus of Number in Chinese.

Secondly, Iljic (1994) turns the argument around by showing that, in any case, the noun itself is unmarked for number. The following example (somewhat adapted) shows that the phrase zhe xin ‘DEM letter/s’ can be referred back to with a singular as well as a plural noun phrase.

(30) ni zhe xin dei cheng yi-xia...
    your this/ese letter/s must weigh a-bit
    ‘this/ese letter(s) of yours must be weighed...
    ... ta chao-zhong-le /liang-feng dou chao-zhong-le
    it overweight /two-CL all overweight-PRF
    ... it is/they are both overweight’

If one considers universal quantification as a kind of pluralization, reduplication of the classifier may be seen as constituting a third indication of the connection between number and the classifier, since reduplication of the classifier yields a universal quantification reading (Paris 1981, 69). The flexibility in this respect is not the same in all Chinese languages, but they all allow for classifier reduplication at least to a very basic degree. Here are examples, one from Mandarin, one from Cantonese.
3.1.4. Individuation

Closely related to the countability function is the “individualizing function” (Croft 1994, 162) of classifiers, a function that is also noticed by Iljic (1994) and Paris (1981), among others. As we just saw in (27) and (28), the canonical classifiers are always singular.

We may rephrase this and state that the classifier singles out one entity from the plurality of entities provided by the semantic representation of the noun in the lexicon; it picks out one instance of what is denoted by N. This is also represented in the Chinese way of saying ‘two books’: it uses the individuating classifier as is shown in (32), not the plural one, as the ungrammaticality of the phrases in (33) asserts.

(32) san ben shu Mandarin
    saN bun zhu Southern-Min
    saam bun syu Cantonese
    three CLvolume book

(33) *san xie shu Mandarin
    *saN se zhu Southern-Min
    *saam di syu Cantonese
    three CLPL book

Thus, the literal translation of ‘three books’ in Chinese is ‘three singular units/instances of book’.

The relevance of this discussion will become clear shortly, when we discuss more generally the functional superstructure of the noun in the following section.

3.2. The functional superstructure of N

3.2.1. What it does

The discussion in the previous sections was limited to classifiers in Chinese. In this section, we want to relate this discussion to the issue of the functional superstructure of the noun more generally, especially because we have reasons to assume that classifiers and D serve similar functions.

Several notions come up in general discussions on the functional domain of the noun phrase. Two of these notions, that seem to be expressed in the nominal domain in all languages of the world, are definiteness and number. All languages have ways of discriminating between definite and indefinite reference. Likewise, they all have ways of distinguishing singular from plural.

Before going into definiteness and number, we would like to change the perspective and, concretely, look at what basic functions D, the head of the functional category DP, has been associated with. We would single out two. First, it has been associated with what one could call a “subordinating” function (Szabolcsi

---

9 As a consequence, men cannot be a plurality marker – contra Li 1999. We disagree with Li for many reasons, one being that her approach does not explain the lack of productivity of men; another reason is that it does no justice to the meaning of men, which is much more a collective marker than a plural marker. See Iljic 1994 and Cheng and Sybesma 1999 for discussion.
In semantic terms, NPs are predicates, which can be turned into arguments by D (type-shifting; Partee 1987). It is only thanks to being embedded in DP that an NP can be used as an argument at all. Secondly, Longobardi (1994) argues that the individuating function we associated with the classifier in Chinese is also a typical D-function. He states (1994, 634) that D has the ability to pick out a single instance of whatever is described by N (see also Higginbotham 1985).

We think that these two functions which D is supposed to perform (individuation, syntactic subordination) are closely related to, or even different manifestations of, a more fundamental property of the DP domain: its deictic property – the property to be able to refer at all.

Generally speaking, in language, there is a division of labor between the lexical domain and the functional domain. The division of labor can be summarized as “lexical units describe, functional units refer”. It can also be described as “lexical units refer to a concept, functional units refer to actual instantiations of that concept in the real world”. The lexical entity dog, for instance, “describes” in the sense that it refers to a concept, i.e. “dogness”. It is only thanks to functional elements like a and the that we can use lexical items like dog to refer to actual instantiations of “dogness” in the real world.

The same division of labor is found in the verbal domain. Bake cookies describes a certain type of event. Embedding it in a deictic category like TP enables one to use it to refer to an actual event in the real world that can be described as “bake cookies”: (John) baked cookies; T explicitly links the lexical phrase bake cookies with a specific event associated to the time axis of the real world.

This division of labor between functional and lexical categories is such a fundamental property of language that it must be part of U.G.: All languages have it.

From the literature it may be deduced that this deictic function is a function mainly associated with D. D individuates and, possibly, by doing so, subordinates. The question that arises is: if this division of labor is such a fundamental property of language, and the deictic function is performed by D, what is going on in languages that lack D?

Before answering this question, we take a look at the nominal phrase in English and French.

### 3.2.2. The D in English and French

Consider the following phrases from English and French. In all these phrases, the determiners (the, a and Ø in English and le, les, un and des in French) presumably perform the deictic function. What else do they do?

(34) a. the boy, the boys
    b. a boy, boys

(35) a. le garçon, les garçons
    them:SG boy thePL boys
    b. un garçon, des garçons
    aM:SG boy aPL boys

In English, the determiner the signals definiteness. It does so in both plural and singular phrases. In other words, the does not give us any information with respect to Number. In English definites, Number is marked on the N. A signals indefiniteness, but also singularity. The plural indefinite does not have an overt determiner in English.

In French, the determiner is responsible for expressing both number (Delfitto and Schroten 1991) and definiteness. Garçon and garçons sound exactly the same: whether we are dealing with plural or singular, definiteness of indefiniteness is marked by the determiner. The singularizing function apparent from a in English seems to be part of le’s function in French as well.10

---

10 In some cases French nouns do make a plural/singular distinction (cheval, chevaux) and in combination with the preposition à the determiner loses its number function: au and aux. Similarly, nouns may express gender, and the gender function of the determiner may be neutralized; both are illustrated by l’étudiant and l’étudiante. These exceptions do not undermine the system of French as described in the text.
When we look at (36) we see that *le* does even more.

(36) a. le garçon  
theM:SG boy  

b. la fille  
theF:SG girl

As Croft (1994) notes, grammatical gender must be seen as a kind of noun classification and in languages such as French, gender is expressed through the determiner.

In short, *D* in French expresses definiteness, number and noun classification. Besides, it has the deictic function we mentioned earlier; it individuates in the sense developed above and makes it possible for an NP to be used as an argument.

In English, *D* performs the deictic function, but only expresses (in)definiteness; it does not express Number and noun classification does not play a role in English. Number in English is expressed on the noun.

3.2.3. Cl in Cantonese

Earlier we posed the question: If U.G. incorporates a describing-referring dichotomy and *D* takes care of the referring deictic function in the nominal domain, what happens in languages that don’t have determiners?

The answer is, of course, that some other functional head will perform that function. When we turn our attention to Cantonese against the backdrop of our discussion of English and French in the previous section, we find that in Chinese the classifier does many things that determiners do in other languages. Consider the basic Cantonese data in (37).

(37) a. bun syu; di syu 
CLvolume book; CLPL book  
‘the/a book; the/Ø books’

b. yat-bun syu; syu  
one-CLvolume book; book  
‘a book; books’

c. go jan; zek gau  
CL person; CL dog  
‘a/the person; a/the dog’

What do these examples tell us? First of all, the fact that these phrases refer means that some element performs the deictic function. Secondly, the fact that, as was shown in the example sentences in the first section, these phrases can be arguments of predicates indicates that some element functions as the subordinator. Third, these clusters of facts show very clearly that the classifier is the locus of number (see the a-examples) as well as classification (compare the classifiers used in the a-examples with the ones used in the c-examples); the individuation function was elaborated on above. The definiteness-indefiniteness contrast is less straightforward, at least in the singular (we discuss this fact below); the plural shows a clear presence-absence contrast, as was the case in English.

In short, all the functions the determiner takes care of in French are performed by the classifier in Cantonese: definiteness, number, individuation, noun classification, subordination and deictism.

This leads to the conclusion that the classifier is the head of a functional projection, ClP, which is in all relevant ways comparable to DP in languages like French and English. (For earlier proposals of ClP, see, for instance, Tang 1990.)
3.3. Conclusion

In this section we have investigated the function of the classifier, in its own right as well as to the background of the more general discussion on the function of the superstructure in the nominal domain. We found that there is one fundamental function to be performed by a functional head in the nominal domain: the deictic function. The lexical NP describes, the functional head deictically refers. We also found that this function is intricately related to the expression of number, definiteness and even noun classification. It is also linked to the more purely syntactic function of making it possible for the lexical NP to be embedded in a predicate as an argument.

In languages with determiners, the deictic function is performed by D. In Chinese, at least in Cantonese, we concluded, it is taken care of by the classifier. The classifier heads its own functional projection, ClP. This leads to the postulation of the following structure (to be qualified below):

\[(38) \quad \text{ClP} \]

\[
\begin{array}{c}
\text{Cl'} \\
2 \\
\text{Cl}^0 \\
\text{NP}
\end{array}
\]

We will see that this is the structure we find in all Chinese languages discussed here. The question is, of course, how we account for the variation we found in section 2.

4. Interpretation and distribution

In section 2 we saw that Bare NPs as well as Cl-NP phrases can be interpreted as definite as well as indefinite. (As we noted, the position in the sentence plays a role in determining the interpretation.) Among the languages we discuss in this chapter, Wenzhou is unique in allowing both interpretations for both. In Mandarin, Bare NPs can have both interpretations, while Cl-NPs are exclusively indefinite. In contrast, in Cantonese, Cl-NPs can have both interpretations, while Bare NPs are restricted to indefiniteness. In Min, which disallows Cl-NPs altogether, Bare NPs can get both readings.

In section 3 we preliminarily postulated the structure in (38) as the structure for nominal phrases in Chinese. In this section we investigate the question what determines the variation we found: Why can some phrases be definite in one position but not in the other? Why can some types of NP be definite in the one language but not in the other?

We start with the definites.

4.1. Definites

4.1.1. Cantonese, Mandarin and Min

Two different types of phrases can be interpreted as definite: Cl-NPs and Bare NPs. Before we turn to Chinese, let us first determine how, in general, definiteness is supposed to arise.

Essentially following the literature, we assume that definiteness arises as the result of the insertion of a certain operator, called the ι operator, into D (Partee 1987). We further assume that the ι operator may be realized as a definite article, as is the case in languages such as English, or may be non-overt, for languages without a definite article. Insertion of the ι operator in D most likely subsequently triggers N-to-D-movement, overtly or non-overtly (see, e.g., Ritter 1989, Longobardi 1994); for enlightening discussion on these matters, see Chierchia 1998.

Let us now turn to Cantonese. In section 3 we reached the conclusion that Cl has many properties in common with D, the singularizing, deictic function being one of them, and we subsequently likened ClP in Chinese-type languages to DP in English/French-type language. We propose that definite Cl-NPs in Cantonese have the structure in (38): the lexical NP is embedded in a functional structure, ClP, the head of
which is filled by an \( \iota \) operator realized as an overt classifier. The overt classifier has exactly the same function as determiners like English \textit{the}: thanks to the \( \iota \) operator, insertion in Cl\(^0\) makes the phrase definite.

As to Mandarin, we suggest that it takes the other option we mentioned: definite Bare NPs also have the structure in (38), but now the \( \iota \) operator in the head of ClP is non-overt (presumably triggering covert N-to-Cl movement).

This means that all definite nominals in Cantonese and Mandarin have the underlying structure in (38). Cantonese fills the Cl\(^0\)-position with an overt classifier, yielding definite Cl-NPs. Mandarin derives definite Bare NPs by inserting the non-overt \( \iota \) operator in Cl\(^0\) (followed by covert N-to-Cl).

Southern-Min, of course, is the same as Mandarin. Its definite Bare NPs are derived in exactly the same way: insertion of the empty \( \iota \) operator in Cl\(^0\), followed by covert N-to-Cl.

We discuss Wenzhou in the following section.

4.1.2. Definites in Wenzhou

Among the languages we discuss here, Wenzhou is exceptional because it allows a definite interpretation for both Bare NPs and Cl-NPs. The definite Bare NPs should be unproblematic: their derivation will be the same as in Mandarin and Min: Cl\(^0\) in their underlying structure (38) hosts an empty \( \iota \) operator, yielding the definiteness.

The definite Cl-NP, on the other hand, may be more problematic because of its extra feature which we have been referring to as tonal neutralization. In definite Cl-NPs, all classifiers with tones belonging to the hi-register subcategory end up being pronounced as a hi-D-tone, all lo-register tones end up as being pronounced as lo-D.

In actual fact, what we observe is a general lowering. If we describe the tones of Wenzhou in terms of a three point scale (H,M,L) instead of a five point scale as was done in table 1, hi-A, hi-B and hi-C can be characterized as H, hi-D as M or L. At the same time, lo-A, lo-B and lo-C can be characterized as M or L, while lo-D is L. In other words, H goes to M or L, M or L end up as L.

We propose that in Wenzhou, the \( \iota \) operator, in addition to being non-overt, can also be realized as a low tone, a non-segmental unit. When the low tone \( \iota \) operator is inserted in Cl\(^0\) it must be supported by an element with a richer phonological (i.e., segmental) matrix, like a classifier. As a result of the fusion between the low tone \( \iota \) operator and the classifier, the classifiers with a tone that is characterizable as H are lowered to M (or L), the ones with an M or L tone are lowered to L. This proposal is in line with the principle that all tones must be borne by a full syllable (see the work by John Goldsmith, e.g. Goldsmith 1976) as well as the principle that morphemes must always be realized — otherwise we wouldn’t know it is there (Lin 1993). In the case at hand, the \( \iota \) operator in Cl\(^0\) has the form of a low tone, and nothing else; as a consequence, in order for the definiteness to be expressed, the tone has to be realized — on the classifier. Interestingly, the original tone of the classifier is reflected in the register: hi-register tones come out as hi-D, lo-register tones as lo-D (except, of course, if the two D-tones are not distinguished; see footnote 12).

If this proposal is correct, it means that the \( \iota \) operator can have a phonological reflex that is anywhere between zero and a lexical, fully segmental element like a determiner or a classifier: it can be realized as something non-segmental as a tone.

Also, the proposal entails that the formation of definites in Wenzhou involves a certain degree of optionality: it can pick either of two manifestations of the \( \iota \) operator (to be discussed further in section 5.2).

---

11 We thank Moira Yip for discussion of the phonological side of the matter.

12 Chen (2000, 476-477) reports that in his informant’s speech, the two D-tones are not distinguished. In Chen’s tone system of Wenzhou, the D tone is characterized as L. (Recall that Chen works with partly different values; see the comment under table 1 in the text.)

13 The lowering rule apparently does not apply to the D-tones themselves.
4.1.3. Summary

To conclude this section on definites, we have seen that all definite nominals in Chinese we discussed have (38) as their underlying structure. The derivation of definites involves the insertion of an ι operator into the head of ClP. The ι operator has different manifestations. It may be non-overt, as is the case in Mandarin and Min and is an option in Wenzhou, or it may be overt, in which case it is either realized as a full lexical element, a classifier, as is the case in Cantonese, or it may be realized as a low tone, as we saw is an option in Wenzhou. In the latter case, the tone has to be provided with a segmental matrix, like a classifier, which has lowering effects on the tone of the classifier involved.

At least two questions arise. (a) What determines the difference between the different languages? For instance, is there any reason why, say, Mandarin cannot be like Cantonese? And where does the optionality in Wenzhou come from? (b) If Cl-NPs and Bare NPs have the underlying structure in (38), how come they can also be interpreted as indefinite? We will answer the first question in section 5, after having answered the second question in the next section.

4.2. Indefinites

The only type of phrase which is invariably indefinite in all languages dealt with in this study is the Num-Cl-NP phrase, the one with an overt numeral. In view of the discussion on definites in the previous section, we assume that the indefinite reading is due to the presence of the Numeral; we return to this below. Let us postulate the following structure for indefinite nominal phrases in Chinese, where NumeP stands for NumeralP (instead of NumP, to avoid confusion with NumberP).

(39)   NumeP
       2
Nume’  2
Nume0  2
ClP
       2
Cl’  2
Cl0  NP

Is there any evidence that (39) is the underlying structure for all different types of indefinite noun phrases, including Cl-NPs and Bare NPs? We think there is.

Longobardi (1994) develops a proposal with respect to the distribution and interpretation of bare nouns in Germanic and Romance. Distributionally, bare nouns in Germanic and Romance are limited to lexically governed positions (in effect, object positions) and interpretationally, they are restricted to an indefinite reading. Longobardi’s proposal comes down to the following. Bare nouns are not really bare: they are, of course, embedded in a fullfledged DP projection, the head of which is empty. The assumption of the empty D helps Longobardi explain both the restricted distribution and the limitations on the interpretation in the following way. First, as the empty D is just like any other empty category in having to be lexically governed, the distribution of bare nouns is limited to lexically governed positions. Secondly, Longobardi argues that an empty D is associated with an existential reading (see also Chierchia 1998).

Turning our attention to indefinite Cl-NP phrases, if they have the same structure as Num-Cl-NPs, i.e. the structure in (39), in which the Numeral is empty, we predict that they are limited to lexically governed positions. As the facts in section 2 show, this is the case: Cl-NPs can have an indefinite interpretation only in object position.

For indefinite Bare NPs, the reasoning and the conclusion are the same. In view of the fact that the Bare

\[14\]

Indefinites with a numeral can also not occur in subject position; this is due to reasons related to existential closure: see Diesing 1992, Cheng 1991 and Tsai 1994, and, for some discussion, Cheng and Sybesma 1999.
NPs with an indefinite reading occur in lexically governed positions only, suggests that they involve an empty category which has to be governed. If it is the case that in Chinese indefiniteness arises as a result of the presence of a numeral, the Bare NP must have a numeral. In short, we assume that indefinite Bare NPs also have the structure in (39); the difference with indefinite Cl-NPs is that in the case of Bare NPs, not only the Numerical head Nume0 is empty, but the Cl0 is empty as well.

In short, assuming the structure in (39) for indefinite Cl-NPs and Bare NPs explains their limited distribution.

Comparing (39) to (38) we see that (39) actually consists of (38) embedded in a NumeP. The structure in (38) being the structure underlying all definite nominals in Chinese, this suggests that the indefinite interpretation arises as a result of the presence of the Numerical. The NumeP, being a quantificational expression, is interpreted as indefinite. “A book” in Chinese languages is literally “[one [the book]]”. To get an indefinite reading, a NumeP is required.

In this respect, there seems to be a difference between languages with articles and those without. As was suggested by Teun Hoekstra (class lectures, fall 1996), nominals in Germanic and Romance languages are quantificational expressions, that is, indefinite, unless they are embedded in a DP. Thus, “the book” in English is in fact “[the [(a) book]]”. Articled languages have indefinite articles (or, in their absence, the numeral ONE) to pick out singularities, while article-less languages only have classifiers for that purpose. Classifiers, however, are very similar to definite determiners, as we saw above.

Before closing off this section, we would like to mention two things. First, it should be noted that definite Cl-NPs and definite Bare NPs do not involve an empty category: in case of the definite Cl-NP, there is no numeral ((38) does not involve a NumeP); in the case of the Bare NP, aside from there being no NumeP, Cl0 is occupied by the 1 operator and N0 as the result of N-to-Cl. Since they do not involve an empty category, they should not be restricted distributionally, and they aren’t.

Secondly, in section 2 we noted that indefinite nouns with an overt numeral can be interpreted as both specific and nonspecific, while indefinite Bare NPs and Cl-NPs can only be nonspecific. In Cheng and Sybesma 1999, 530-532, we supply ample evidence that indefinite Cl-NPs involve an empty numeral and that they, and indefinite Bare NPs, are excluded from contexts in which a specific interpretation is the only possible option for an indefinite; we have seen some such contexts above, e.g. (3b). The fact that indefinite Cl-NPs and indefinite Bare NPs may only be nonspecific, while fullfledged Num-Cl-NPs may be both specific and nonspecific is likely to be related to the empty Numerical in the former: an empty Numerical leads to a nonspecific interpretation. A possible explanation for the difference between an empty Numerical and an overt Numerical is that the latter is a fullfledged quantifier and as such can undergo quantifier raising (QR), yielding a specific reading. In contrast, an empty Numerical lacks the QR option. Instead, it relies on the presence of existential closure to supply the existential quantification, yielding a narrow scope nonspecific reading (cf. Diesing 1992).

4.3. Summary

These are the structures postulated for definite and indefinite nominal phrases in Chinese: all indefinites (Num-Cl-NPs, Cl-NPs, Bare NPs) have the structure in (40a) (= (39)), all definite structures (Cl-NPs, Bare NPs) have the structure in (40b) (= (38)). In the indefinite case of (40a), Nume0 and Cl0 may be left empty, in the definite (40b), Cl0 is filled by the 1 operator (possibly realized as an overt classifier) and the covertly moved N0.

---

15 We assume that movement of N to Cl (or Nume, for that matter) would only take place if triggered.
5. How to account for the variation

The four varieties of Chinese dealt with here differ from one another in the following ways:

1. Mandarin and Min do not have definite Cl-NPs, they have definite Bare NPs; for Cantonese exactly the opposite is true.
2. Mandarin has indefinite Cl-NPs, like Cantonese and Wenzhou; Min does not: it is the only variety with no Cl-NPs at all.
3. Cantonese and Wenzhou are the only varieties with definite Cl-NPs, but they differ in that in Wenzhou the tone of the classifier is affected.
4. Wenzhou differs from all others in that it allows a definite reading for both Cl-NPs and Bare NPs; all other languages allow a definite reading for just one of the two.

We discuss some of these differences below.

5.1. Mandarin and Min vs. Cantonese

We saw that the derivation of definite nominals involves the $\iota$ operator, the difference between the languages discussed in this chapter resulting from the different manifestations the $\iota$ operator may take on. Disregarding Wenzhou for the moment, we see that definite nominals either are Cl-NPs (as in Cantonese) or are Bare NPs (as in Mandarin and Min): Cantonese involves the insertion of an overt classifier, just like English inserts its overt determiner, while Mandarin and Min have no overt reflex of the $\iota$ operator.

From a general point of view it seems that the option favored by Cantonese is the preferred one (the default). That is to say, in his discussion on noun phrases in English and other languages, Chierchia (1998) suggests that, as far as definiteness is concerned, expressing it overtly is favored over doing it covertly. In other words, if, in principle, there is a choice, languages opt for expressing definiteness overtly, using a definite article (or, we may add now, a classifier). Since the Cantonese option involves insertion of a classifier in Cl$^i$, this embodies the preferred procedure. This explains why in Cantonese this is the only option. At the same time, it raises the question what is wrong with Mandarin and Min: What bars them from opting for the preferred choice?

In this context we would like to point at two facts. First of all, in Min, it is impossible to have an overt classifier without a numeral: as we have mentioned several times, Min has no Cl-NPs at all. The second fact is that in Mandarin, Cl-NPs are always indefinite. If our assumption that indefinites have the underlying structure in (40a) is correct, this means that Mandarin overt classifiers also cannot occur without a numeral, the difference between Mandarin and Min being that Min cannot have empty numerals.

Let us phrase this in the form of a restriction on the appearance of overt classifiers in these varieties of Chinese:

(41) In Mandarin and Min, overt classifiers are always accompanied by a numeral. (In Min, the numeral must be overt, in Mandarin it may be overt or nonovert.)

Cantonese does not have this property. Although we have no deeper explanation for this difference between
Cantonese on the one hand and Mandarin and Min on the other, the restriction explains why it is impossible for Mandarin and Min to get definite nominals in the preferred way. After all, the preferred way involves the insertion of an overt classifier in the head of ClP. For Mandarin and Min, overt classifiers always come with a numeral and numerals lead to indefiniteness.

5.2. Optionality in Wenzhou

It is not clear how Wenzhou, having both definite Bare NPs (like Mandarin and Min) and definite Cl-NPs (like Cantonese), fits into this picture. Since it does not have the restriction in (41) (as is clear from the data in section 2.2), there is no reason why it should not be like Cantonese.

To be sure, Wenzhou does have definite Cl-NPs, but the tone of the classifier is lowered. Above, we claimed that this is the result of a fusion between a non-segmental, strictly tonal \( \imath \) operator and the classifier. In other words: we analyzed definite Cl-NPs in Cantonese and Wenzhou as entirely different. In definite Cl-NPs in Cantonese the Cl is the classifier in its full form – a segmental \( \imath \) operator. In the Wenzhou definite Cl-NPs, on the other hand, the classifier is only there to provide the non-segmental \( \imath \) operator with segmental material.

In section 4.1.2, we suggested that the \( \imath \) operator can have a phonological manifestation that is anywhere between zero and a fully segmental lexical element like a determiner or a classifier; after all, it can also manifest itself as something non-segmental (a low tone, for instance). Let us be less liberal and state that there are three options: segmental, non-segmental and empty.

In view of the facts of Cantonese and Wenzhou, we may conclude that only the segmental manifestation counts as fully overt for the purposes of expressing definiteness as discussed above in the context of Chierchia’s hypothesis that definiteness is preferably expressed overtly. Syntactically, the non-segmental tone does not count as “overt”.

This means that the optionality in expressing definiteness displayed by Wenzhou does not involve the preferred, overt option; it is between two non-overt options. That is why it can have optionality at all. As Chierchia states, if there is a choice, and the overt option is one of the alternatives, then that is, really, the only option, the default. Then there can be no optionality.\(^\text{16}\)

The answer why Wenzhou is not like Cantonese, then, comes down to the fact that the choice it has for expressing definiteness does not involve the overt option. We don’t know why this is the case.

5.3. Parameters discussed in this chapter

The first parameter to be mentioned is the one that distinguishes “languages with articles” from “languages with classifiers”. Several differences between these two types of languages seem to fall out from one main difference, the fact discussed in section 4.2, that whereas in article languages definites are indefinites-turned-definites, languages with classifiers derive indefinites on the basis of definites. This difference is the consequence of the latter type of language having no indefinite article.

Within the domain of Chinese, the variation may be reducible to the following parameters. The first is whether or not definiteness is expressed by an segmental \( \imath \) operator in Cl\(^0\), i.e., in the form of a fullfledged classifier, which would set Cantonese apart from the other varieties. Another point of variation is whether or not it is possible to have an overt classifier without a numeral (setting apart Mandarin and Min from Wenzhou and Cantonese). Thirdly, Mandarin, Wenzhou and Cantonese can have empty numerals, whereas Min cannot. The parameters can be charted out as follows. The claim that the non-overt \( \imath \) operators involve a (phonologically speaking) truly empty one and one in the manifestation of a low tone is not considered in the table.

\(^\text{16}\) The restriction in (41) bars Mandarin and Min opting for both the segmental and the non-segmental-only \( \imath \) operators. At the same time, the reasoning in the text leaves open the possibility that they pick the empty one for reasons not related to (41). After all, we do not have a clear idea as to what factors play a role in determining the choice for any of the three \( \imath \) operators.
TABLE 3

<table>
<thead>
<tr>
<th></th>
<th>Classif. or Article</th>
<th>(\tau) operator realized segmentally</th>
<th>Overt classifier oblig. w. numeral?</th>
<th>Can numeral be empty</th>

</tbody>
</table>

It is conceivable that some of these parameters are related to the status of the classifier at a deeper level. As such they may possibly be connected to phenomena other than the ones discussed in this chapter. There may be a deeper difference, distinguishing “weak classifiers” from “strong classifiers”. Aside from the question as to whether they can occur without a numeral or not, we should consider the freedom of reduplication of the classifier (which seems, at a first impression, freer in Cantonese and Wenzhou than in Mandarin and Min) as well as the question whether they are used as the element that links the modifier to its noun or not (which is the case in Cantonese and some varieties of Wu, but not in Mandarin and Min). More research in this area is necessary to see whether there is such a "deep" parameter or not.
